An advertisement for Oxford Instruments Atomic Force Microscopy (AFM) systems. The background is dark blue with a lighter blue gradient. On the left, there is a black mobile phone and a white desktop computer. In the center, there is a white AFM instrument. Text on the left side reads: 'You don't still use this cell phone or this computer'. Text in the center reads: 'Why are you still using an AFM designed in the 80's?'. Text on the right side reads: 'It is time to upgrade your AFM', 'Minimum \$20,000 trade-in discount for purchases before August 31st', and 'Asylum Research is today's technology leader in AFM'. At the bottom right, there is the Oxford Instruments logo and the tagline 'The Business of Science®'. The email address 'dropmyoldAFM@oxinst.com' is also present.

SmScO₃ thin films as an alternative gate dielectric

Samarium scandate thin films deposited on (100) Si have been investigated structurally and electrically. Rutherford backscattering spectrometry and transmission electron microscopy results show that the films are stoichiometric, amorphous, and smooth. X-ray diffraction analysis indicates that SmScO₃ starts to crystallize at 900 °C. Capacitance and leakage current measurements reveal C-V curves with negligible hysteresis, a dielectric constant around 29 for 6 nm thick films, low leakage current densities in the range of 10⁻⁷ A/cm², an effective oxide charge density of ~5 × 10¹¹ (cm⁻²), and an interface trap density of 4.5 × 10¹¹ (eV cm²)⁻¹. © 2008 American Institute of Physics. [DOI: 10.1063/1.2968660]

The dielectric SiO₂ has been the key to the tremendous improvements in Si-based metal-oxide-semiconductor (MOS) device performance over the past four decades. It has, however, reached its limit in terms of scaling since it exhibits a leakage current density higher than 1 A/cm² and does not retain its intrinsic physical properties at thicknesses below 1.5 nm.^{1,2} In order to overcome these problems and keep Moore's law ongoing, the use of higher dielectric constant (κ) gate oxides has been suggested. These high- κ materials must satisfy numerous requirements including high κ , large band gap and band offsets, low leakage current density, low interface trap density, high breakdown strength, acceptable reliability, and additionally thermal stability in contact with silicon. Recently, Intel reported the first 45 nm microprocessors using a hafnium-based gate oxide together with an appropriate metal gate material. The transistors in these microprocessors exhibit an order of magnitude lower gate leakage than transistors with an SiO₂ gate dielectric.³ Tomida *et al.* observed that Hf_(1-x)Si_xO₂ shows different κ values depending on the crystallization phase.⁴ They observed that amorphous Hf_(1-x)Si_xO₂ shows a κ value around 20; however, for monoclinic phase, the κ value is 15 and as they increased the temperature and changed the crystallization phase from monoclinic to tetragonal the κ value increased to 27. Moreover, Böске *et al.*⁵ and Migita *et al.*⁶ obtained a κ of 36 and an even higher κ value for tetragonal and cubic HfO₂, respectively. However the κ of amorphous hafnium-based oxides varies between 10 and 20.^{7,8} In contrast, rare earth (RE) scandates (REScO₃, RE=Gd, Dy, La) show higher κ and, therefore, have attracted significant attention for high- κ applications.⁹⁻¹³ The amorphous RE scandates have κ between 20 and 30 and the crystalline phases have κ over 30.¹² Christen *et al.* observed band gaps higher than 5.5 eV for these REScO₃ oxides and varying crystallization temperatures depending on the RE atomic number and the Goldschmidt tolerance factor.¹² According to their results, the crystallization temperature of SmScO₃ (750 °C) lies intermediate between those of LaScO₃ (650 °C) and GdScO₃

(800 °C), however, among them it has the highest κ when crystallized. So far there are no experimental results about the application of amorphous SmScO₃ as a gate dielectric. The aim of this paper is therefore to establish the properties of amorphous SmScO₃ thin films concerning the above-mentioned requirements for high- κ materials.

SmScO₃ films with thicknesses ranging from 6 to 62 nm were deposited by pulsed-laser deposition (PLD) using a stoichiometric ceramic target. RCA cleaned *p*-type (100) Si wafers were used as substrates. Prior to film deposition the wafers were heated to 400 °C and the deposition was carried out in 2 × 10⁻³ mbar O₂ with a fluence of 2.5 J/cm² and a pulse rate of 10 Hz from a 248 nm (KrF) excimer laser. After the deposition, the structure, stoichiometry, and thermal stability of the films were investigated using Rutherford backscattering spectrometry (RBS), transmission electron microscopy (TEM), and x-ray diffraction (XRD).

For electrical characterization, MOS capacitors were fabricated. 70 nm thick Pt top contacts were deposited by electron beam evaporation through a shadow mask with areas between 2 × 10⁻⁴ and 11.5 × 10⁻⁴ cm². An Ohmic backside contact was realized by depositing 120 nm Al. Finally, the samples were annealed in forming gas (90% N₂ + 10% H₂) for 13 min at 450 °C to improve their electrical properties.

High frequency C-V measurements were carried out using an impedance analyzer (HP 4192A) at 100 kHz. The work function of the metal gate and the effective charge density in the oxide were obtained from the high frequency C-V results. The density of the interface trap states (D_{it}) was calculated using Terman's method.¹⁴ Finally, leakage current measurements were performed using a semiconductor parameter analyzer (HP 4155B).

The stoichiometry and thickness of the films were determined by RBS. Simulation of the RBS data using the rump program¹⁵ reveals that the films have the desired stoichiometry with a ratio of Sm:Sc:O=1:1:3.

A cross-sectional TEM image of a 49 nm thick SmScO₃ film on Si (100) (Fig. 1) shows an amorphous and smooth film on Si. The figure also indicates the existence of an interfacial layer between the silicon and the high- κ dielectric

^{a)}Electronic mail: eylemdurgun@gmail.com.

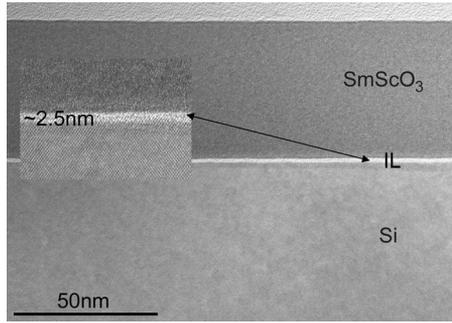

FIG. 1. Cross-sectional TEM micrograph of a 49 nm thick SmScO_3 film deposited on (100) Si. The inset shows a close-up of the interlayer, which has a thickness of about 2.5 nm.

with a thickness of 2.5 nm. The growth of the interfacial layer is probably related to the oxidation of the silicon surface during PLD growth.

In order to study the thermal stability of the SmScO_3 grown at 400 °C, rapid thermal annealing in ultrapure N_2 was performed at atmospheric pressure and different temperatures ranging from 700 to 1100 °C for 10 s. Figure 2 shows the XRD patterns of a 22 nm thick SmScO_3 film for different annealing temperatures. It is apparent that the as-deposited film is amorphous, in agreement with the TEM results. The film remains amorphous up to 800 °C and the crystallization of the orthorhombic SmScO_3 phase starts at 900 °C, as indicated by the arrows identifying SmScO_3 reflections. The value for the onset of crystallization is higher than that for HfO_2 (Ref. 16) and comparable to Hf silicates.¹⁷ It is, however, lower than for DyScO_3 and GdScO_3 .¹⁰

Figure 3 shows the capacitance normalized to the gate area versus gate voltage for SmScO_3 films with different thicknesses. The C - V curves are smooth and free of humps. Double sweep measurements from inversion to accumulation and back were carried out at a frequency of 100 kHz with a 3 s hold time for each measuring point. Negligible counter clockwise hysteresis indicates that these samples contain a low density of positive trap charges, Q_{ot} , in the range of $\sim 10^{10} \text{ cm}^{-2}$, as estimated from the simple formula, $Q_{\text{ot}} = (C_{\text{ox}}/q)\Delta V_{\text{FB}}$,¹⁸ where C_{ox} is the accumulation capacitance normalized to the gate area, q is the electron charge, and ΔV_{FB} is the voltage shift from the reverse bias measurement to the forward one.

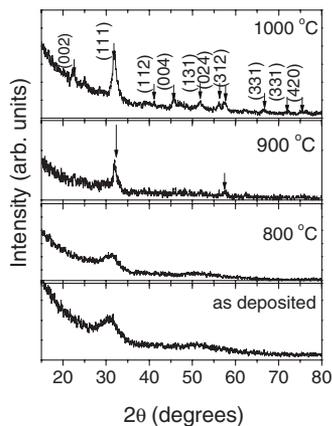

FIG. 2. XRD patterns of a ~ 22 nm thick, as deposited SmScO_3 film grown on (100) Si, together with those after annealing at different temperatures in 1 atm N_2 gas for 20 s.

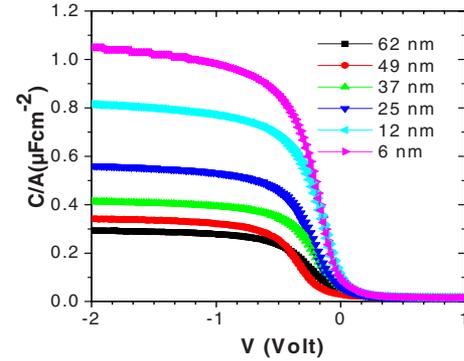

FIG. 3. (Color online) Capacitance normalized to the gate area vs gate voltage of Pt/ SmScO_3 /Si MOS capacitors with different oxide thicknesses.

Using the curves shown in Fig. 3, the capacitance equivalent thickness (CET) was extracted from the capacitance in the accumulation region C_{acc} as $\text{CET} = A\epsilon_0\kappa_{\text{SiO}_2}/C_{\text{acc}}$, where A is the gate area, ϵ_0 is the permittivity of vacuum and κ_{SiO_2} the dielectric constant of SiO_2 . Figure 4 shows a plot of the CET versus oxide thickness t_{ox} . From the slope of the linear fit, it is possible to extract the dielectric constant of the films disregarding the contribution of the interfacial layer. The κ thus obtained for amorphous SmScO_3 is ~ 29 . The intercept of the line with the CET axis represents the electrical thickness of the lower- κ interfacial layer, which is found to be 2.5 nm. This value is in agreement with the physical interfacial layer thickness observed by TEM indicating that this layer has a κ comparable to SiO_2 and thus likely is SiO_2 .

The flatband voltage (V_{FB}) of the samples has been extracted from the comparison between the ideal C - V curves and experimental ones obtained from the capacitors exposed to forming gas annealing at 450 °C. The sample with a 6 nm thick SmScO_3 oxide layer has a -0.1 V flatband shift and as the thickness of the oxide layer increases the flatband voltage shifts to more negative voltages. In order to evaluate the effective oxide charge density (N_{eff}) and the effective work function of the Pt metal gate ($\Phi_{m,\text{eff}}$), $V_{\text{FB}} + \Phi_s$ versus CET was plotted in Fig. 5, where Φ_s is the work function of the silicon. V_{FB} can be expressed as¹⁹

$$V_{\text{FB}} = \Phi_{m,\text{eff}} - \Phi_s - qN_{\text{eff}}\text{CET}/\epsilon_0\kappa_{\text{SiO}_2},$$

where N_{eff} does not change with the oxide layer thickness.

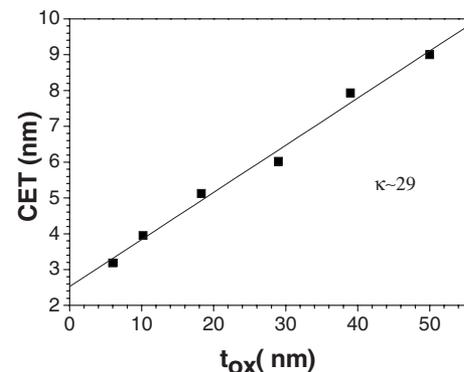

FIG. 4. Calculated CET vs t_{ox} of Pt/ SmScO_3 /Si MOS capacitors. The slope of the best-fit line indicates that $\kappa \sim 29$ and its intercept at 2.5 nm on the CET axis corresponds to the electrical thickness of the lower- κ interfacial layer.

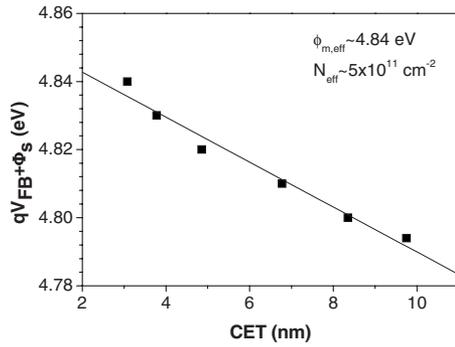

FIG. 5. $V_{FB} + \Phi_s$ vs CET. The intercept of the best-fit line on the $V_{FB} + \Phi_s$ axis gives $\Phi_{m,eff}$ and the slope N_{eff} .

From the intercept of the $V_{FB} + \Phi_s$ axis, $\Phi_{m,eff}$ was found to be 4.84 eV. This value satisfies the work function requirement for a *p*-type MOS field-effect transistor. From the slope of the curve N_{eff} was evaluated to be $5 \times 10^{11} \text{ cm}^{-2}$. Such a low charge density indicates a low concentration of defects in the oxide layer.

Another important issue for MOS capacitors is the quality of the high κ /Si interface. To evaluate the quality of the Si/SmScO₃ interface after forming gas annealing, D_{it} levels were calculated using Terman's method. The values are $\sim 4.5 \times 10^{11} (\text{eV cm}^2)^{-1}$ and do not show a clear dependence on the oxide thickness, as expected. Finally, the leakage current density of the samples was measured. For the sample with a 6 nm thick SmScO₃ it is in the range of 10^{-7} A/cm^2 and, for thicker films, it is even below the detection limit of the measurement system for the contact size used.

We have investigated the thermal stability and electrical properties of SmScO₃ thin films and their interface to Si (100). The films remain amorphous on Si up to 800 °C and start to crystallize at 900 °C. The results indicate low oxide charge and interface trap charge densities in the range of $5 \times 10^{11} \text{ cm}^{-2}$ and $4.5 \times 10^{11} (\text{eV cm}^2)^{-1}$, respectively. Very smooth *C-V* curves with negligible hysteresis were recorded and a κ value of ~ 29 was extracted from the electrical mea-

surements. The films reveal low leakage current densities in the range of 10^{-7} A/cm^2 for 6 nm thick film. It can be concluded that amorphous SmScO₃ shows promising properties as an alternative high- κ gate dielectric, which might allow it to be used in future integrated circuits.
